

Campus Relay Growth Plan

NxtWave Growth Intern challenge | Seven-day simulation | No campaign executed

Working asset: <https://campus-relay-growth.vercel.app>

Proposed offer: Free online workshop, “Build Your First AI Project in 60 Minutes.” Date, instructor and actual workshop projects have not been confirmed.

1. Understand the Student

Who exactly are you targeting?

Final-year engineering students graduating in 2027, across CSE, IT, ECE, EEE, Mechanical and Civil branches, who want a first practical AI project they can explain. The plan does not assume access to a particular campus.

Why would they care?

A small project connected to their branch or own problem is more useful than a broad “learn AI” claim. The preview shows sample input, a visible first output, a 60-minute starter path, a limitation and an outline they can take away. It does not promise an advanced or validated model.

What would make them register?

A credible link between the project they just explored and the proposed free online workshop: they could learn to build a first output using a starter like this. The date, instructor and actual syllabus need organiser confirmation. In this assessment demo, the registration and receipt are fictional.

Campus Relay demonstrates that path: a student types an idea, answers two contextual AI follow-ups, compares three projects, then inspects a selected flow, hypothetical use and cited comparable workflow. Guided questions and curated examples are labelled fallbacks when live AI is unavailable.

Where the registrations could come from

Priority	Channel and action	Why it fits	Planning yield
1	Ask 20 relevant coding clubs, IEEE branches, GDG on Campus chapters and hackathon groups to share an approved 20-second project demo and tracked link in the spaces their members actually use.	Engineering communities already gather students interested in building; a club lead can explain the offer in context.	$20 \times 15 = 300$
2	Ask eight department or career teams for one final-year class announcement or targeted email with a simple project example.	The message reaches the intended year and branch through a trusted academic channel.	$8 \times 20 = 160$
3	Ask ten student project creators or clubs to show the Matchmaker and one starter result, each with a distinct link.	A visible output makes the one-hour scope easier to judge than a broad promotional claim.	$10 \times 10 = 100$
Optional	Offer a one-to-one “build together” invitation after registration. The friend sees a project with roles for both branches.	A specific shared task gives a natural reason to invite a peer without a cash incentive.	$100 \text{ invites} \times 50\% = 50$

These figures are planning assumptions, not observed reach or conversion. They total 610 gross registrations. After an assumed 18% reduction for overlap, duplicates and ineligible years (about 110), the stretch target is 500 unique eligible registrations. At 60% of planned channel yield, the same model gives roughly 300, so partner participation and conversion must be checked early. I would use first-touch tracked links to attribute one primary source per registration and keep referral assists separate.

Budget ceiling: ₹2,000. Reserve ₹800 for fixed creator/demo production, ₹400 for visuals and captions, up to ₹200 for hosting, and the remainder (₹600–₹800) as contingency. There is no payment per registration. Actual campaign spend is ₹0 because this is a simulation.

Seven-day operating plan

Day 1: confirm the date, instructor, workshop content and permitted claims; prepare the short demo and partner copy. Days 2–3: test the three channel groups with distinct links and two approved message variants. Days 4–5: inspect visit-to-form and form-to-registration drop-off, improve the weakest step and offer the optional friend invite. Day 6: focus effort where eligible conversion is strongest and check source overlap. Day 7: deduplicate, verify declared eligibility and report the target versus the actual result, including any shortfall. Planning checkpoints are 120 by day 3 and 300 by day 5; neither has been achieved or measured.

What the asset measures and what I would test

The demo stores fictional @example.com registrations in isolated workspaces and displays source, form-start and eligible-count denominators in a separate Growth desk. Seed records are labelled synthetic. A registration is not attendance, and a declared 2027 engineering year is not independent student verification.

Test 1 — Personalised preview. Hypothesis: seeing a project shaped by branch and the student's own idea increases sign-up intent. Test: show a generic workshop summary to arm A and the Matchmaker preview to arm B, assigned before exposure. Metric: unique eligible registrations divided by unique exposed visitors in each arm; inspect preview-to-form drop-off.

Test 2 — Concrete take-home. Hypothesis: a tangible starter increases perceived value. Test: compare a broad project description with a project flow, downloadable outline and next steps. Metric: unique eligible registrations divided by unique exposed visitors in each arm; review whether students understand the outline is a starter, not a completed project.

Test 3 — Shared-project invitation. Hypothesis: a friend invite with distinct roles brings more valid peer registrations than a generic invite. Test: offer both versions after an original registration. Metric: new eligible referred registrations divided by original registrants offered each version; separately track opens and rejected duplicate or self-referral attempts.

These tests are proposals. The desk illustrates the denominators with fictional records; it does not run random assignment or provide evidence of uplift or statistical significance.

Reflection

What changed between your first idea and final solution?

The first idea was a generic workshop page. I wanted students to see a small project relevant to their own problem before registering, so Campus Relay became a conversational Matchmaker with three selectable project recommendations, a fictional registration and friend-invite journey, and a Growth desk that tracks unique eligible registrations by source. The project previews are proposals, not a confirmed NxtWave syllabus.

If you had another 24 hours, what would you improve?

Today the app explains a first-hour project but does not let a student run it. I would make one selected starter playable in the browser: edit a synthetic input, see a real first output, then download the steps to recreate it. That is a concrete proof of the proposed one-hour promise. I would ask five consenting final-year students whether they can explain the result and the workshop offer, fix the confusing step, and confirm all workshop claims with the organiser before outreach.

What did AI suggest that you rejected and why?

AI first offered mostly fixed, branch-aware follow-up questions. I rejected them because a student could type an original idea without receiving questions that genuinely responded to it. The final chat uses two bounded, contextual AI follow-ups. I also rejected a suggested ₹50-per-referral reward: it was absent from the plan and could quickly consume the ₹2,000 budget.
