

Campus Relay Growth Plan

NxtWave Growth Intern challenge | Seven-day simulation | No campaign executed

Working asset: <https://campus-relay-growth.vercel.app>

Proposed offer: Free online workshop, “Build Your First AI Project in 60 Minutes.” Date, instructor and actual workshop projects have not been confirmed.

Who would register, and why

I would target students in their final year of engineering, especially those graduating in 2027 across CSE, IT, ECE, EEE, Mechanical and Civil branches. A short project they can demonstrate and explain is more concrete than a generic invitation to “learn AI.” The main obstacle is credibility: an hour cannot deliver an advanced, validated model. The offer therefore shows a realistic starter input, a visible first output, a 60-minute build path and a limitation before asking for registration.

Campus Relay is the working example of that message. A student chooses a branch and challenge or writes an idea. Two bounded AI follow-up questions ask who would use it and what a first result could show. The app recommends three small projects. Selecting one reveals an input-to-output flow, a hypothetical use case, a cited comparable real-world workflow and a downloadable starter outline. If live AI is unavailable, clearly labelled guided questions and curated examples keep the experience usable. The examples are proposals, not the approved workshop syllabus.

Where the registrations could come from

Priority	Channel and action	Why it fits	Planning yield
1	Ask 20 relevant coding clubs, IEEE branches, GDG on Campus chapters and hackathon groups to share an approved 20-second project demo and tracked link in the spaces their members actually use.	Engineering communities already gather students interested in building; a club lead can explain the offer in context.	$20 \times 15 = 300$
2	Ask eight department or career teams for one final-year class announcement or targeted email with a simple project example.	The message reaches the intended year and branch through a trusted academic channel.	$8 \times 20 = 160$
3	Ask ten student project creators or clubs to show the Matchmaker and one starter result, each with a distinct link.	A visible output makes the one-hour scope easier to judge than a broad promotional claim.	$10 \times 10 = 100$
Optional	Offer a one-to-one “build together” invitation after registration. The friend sees a project with roles for both branches.	A specific shared task gives a natural reason to invite a peer without a cash incentive.	$100 \text{ invites} \times 50\% = 50$

These figures are planning assumptions, not observed reach or conversion. They total 610 gross registrations. After an assumed 18% reduction for overlap, duplicates and ineligible years (about 110), the stretch target is 500 unique eligible registrations. At 60% of planned channel yield, the same model gives roughly 300, so partner participation and conversion must be checked early. I would use first-touch tracked links to attribute one primary source per registration and keep referral assists separate.

Budget ceiling: ₹2,000. Reserve ₹800 for fixed creator/demo production, ₹400 for visuals and captions, up to ₹200 for hosting, and the remainder (₹600–₹800) as contingency. There is no payment per registration. Actual campaign spend is ₹0 because this is a simulation.

Seven-day operating plan

Day 1: confirm the date, instructor, workshop content and permitted claims; prepare the short demo and partner copy. Days 2–3: test the three channel groups with distinct links and two approved message variants. Days 4–5: inspect visit-to-form and form-to-registration drop-off, improve the weakest step and offer the optional friend invite. Day 6: focus effort where eligible conversion is strongest and check source overlap. Day 7: deduplicate, verify declared eligibility and report the target versus the actual result, including any shortfall. Planning checkpoints are 120 by day 3 and 300 by day 5; neither has been achieved or measured.

What the asset measures and what I would test

The demo stores fictional @example.com registrations in isolated workspaces and displays source, form-start and eligible-count denominators in a separate Growth desk. Seed records are labelled synthetic. A registration is not attendance, and a declared 2027 engineering year is not independent student verification.

Test 1 — Personalised preview. Hypothesis: seeing a project shaped by branch and the student's own idea increases sign-up intent. Test: show a generic workshop summary to arm A and the Matchmaker preview to arm B, assigned before exposure. Metric: unique eligible registrations divided by unique exposed visitors in each arm; inspect preview-to-form drop-off.

Test 2 — Concrete take-home. Hypothesis: a tangible starter increases perceived value. Test: compare a broad project description with a project flow, downloadable outline and next steps. Metric: unique eligible registrations divided by unique exposed visitors in each arm; review whether students understand the outline is a starter, not a completed project.

Test 3 — Shared-project invitation. Hypothesis: a friend invite with distinct roles brings more valid peer registrations than a generic invite. Test: offer both versions after an original registration. Metric: new eligible referred registrations divided by original registrants offered each version; separately track opens and rejected duplicate or self-referral attempts.

These tests are proposals. The desk demonstrates assignment and denominator logic with fictional records; it provides no evidence of uplift or statistical significance.

What changed and the next 24 hours

The initial idea was a generic workshop page. The final asset makes the promise concrete through a conversational project preview and connects that preview to a measurable registration and peer-invite journey. With another 24 hours, I would verify workshop facts with the organiser, ask a small consented group of final-year students and a domain mentor to assess the one-hour projects, and revise the weakest observed step before any real outreach.
